13. ABSTRACT (Maximum 200 words) Floristic quality assessment can be used to identify natural areas, to facilitate comparisons among different sites, to provide long-term monitoring of natural area quality, and to evaluate habitat management and restoration efforts. To facilitate the use of floristic quality assessment in North Dakota, South Dakota (excluding the Black Hills), and adjacent grasslands, we developed a species list and assigned coefficients of conservatism (C values; range = 0 to 10) to each plant species in the region's flora. The C values we assigned represented our collective knowledge of the patterns of occurrence of each plant species in the Dakotas and our confidence that a particular taxon is natural-area dependent. Because state boundaries usually do not follow ecological boundaries, the C values we assigned should be equally valid in nearby areas with the same vegetation types. Of the 1,584 taxa we recognized in this effort, 275 (17%) were determined to be nonnative to the region. We assigned C values of 4 or higher to 77% of our native taxa, and the entire native flora had a mean C value (\bar{C}) of 6.1. A floristic quality index (FQI) can be calculated to rank sites in order of their floristic quality. By applying the coefficients of conservatism supplied here and calculating \bar{C} and FQI, an effective means of evaluating the quality of plant communities can be obtained. Additionally, by repeating plant surveys and calculations of \bar{C} and FQI over time, temporal changes in floristic quality can be identified.

Abstract

Floristic quality assessment can be used to identify natural areas, to facilitate comparisons among different sites, to provide long-term monitoring of natural area quality, and to evaluate habitat management and restoration efforts. To facilitate the use of floristic quality assessment in North Dakota, South Dakota (excluding the Black Hills), and adjacent grasslands, we developed a species list and assigned coefficients of

conservatism (C values; range = 0 to 10) to each plant species in the region's flora. The C values we assigned represented our collective knowledge of the patterns of occurrence of each plant species in the Dakotas and our confidence that a particular taxon is natural-area dependent. Because state boundaries usually do not follow ecological boundaries, the C values we assigned should be equally valid in nearby areas with the same vegetation types. Of the 1,584 taxa we recognized in this effort, 275 (17%) were determined to be nonnative

to the region. We assigned C values of 4 or higher to 77% of our native taxa, and the entire native flora had a mean C value (\bar{C}) of 6.1. A floristic quality index (FQI) can be calculated to rank sites in order of their floristic quality. By applying the coefficients of conservatism supplied here and calculating \bar{C} and FQI, an effective means of evaluating the quality of plant communities can be obtained. Additionally, by repeating plant surveys and calculations of \bar{C} and FQI over time, temporal changes in floristic quality can be identified.

Key Words: floristic quality assessment, native plants, natural area assessment, natural area monitoring, North Dakota, plant community evaluation, restoration evaluation, plant species checklist, South Dakota.

Introduction

The natural landscape of North and South Dakota has been modified extensively since pre-European settlement. Large tracts of land have been tilled and put into agricultural production; wetlands have been drained, filled, and farmed; rangelands have been grazed by domestic livestock at timings and intensities that do not match those of native herbivores; and natural fires have been suppressed. Consequently, remaining natural areas display varying degrees of quality because of habitat alterations, and many of the region's native plant species have been reduced or eliminated from vast areas where they formerly occurred. As habitats have been altered, plant species adapted to these habitats have been replaced by other (often nonnative) species better suited to the new ecological conditions. As pressures to develop remaining natural areas continue, so does interest in preserving, restoring, and managing them. Effective methods are needed to identify areas of high floristic quality for preservation and to evaluate the effectiveness of current restoration and management efforts.

Swink and Wilhelm (1979, 1994) developed and later refined a system (floristic quality assessment) for assessing the quality of natural areas in the Chicago region of Illinois. Their system was based on the concept that plant species display varying degrees of tolerance to disturbance, as well as varying degrees of fidelity to specific habitat integrity. They termed this tolerance and fidelity "species conservatism" and assigned each native plant species in the Chicago region a coefficient of 0 to 10 based on its conservatism relative to other native species in the region's flora. Given the assumption that the floristic quality of an area is directly related to its richness in conservative species

(Wilhelm and Ladd, 1988), the assigned coefficients of conservatism (C values), together with a list of native plant species present in an area, can be used to index the floristic quality of that area (Swink and Wilhelm, 1994). Subsequently, floristic quality assessment has been expanded to include Michigan, Missouri, the remainder of Illinois, and northern Ohio (Ladd, 1993; Andreas and Lichvar, 1995; Herman and others, 1997; Taft and others, 1997), and interest to expand the effort to other regions is growing. Here we provide C values for plant species of North Dakota and South Dakota, excluding the Black Hills, (hereafter referred to as the Dakotas) to facilitate the use of floristic quality assessment in this region and adjacent grasslands.

Methods

Assignment of coefficients

At an initial meeting of scientists and land managers in November 1999, we determined that the development of a species list with standardized C values for the Dakotas' flora would improve efforts to assess the quality of remnant natural areas and aid evaluations of restoration and management efforts. The Northern Great Plains Floristic Quality Assessment Panel was formed to develop this checklist by using the "Atlas of the Flora of the Great Plains" and the "Flora of the Great Plains" (Great Plains Flora Association, 1977, 1991) as primary reference sources. In January 2000, the panel met for a 3-day workshop at the North Dakota State University Herbarium, in Fargo, North Dakota, where we assigned a C value to each taxon on the checklist (see page 7).

We attempted to include all species naturally occurring in plant communities of the Dakotas on our checklist. However, the listing of taxa is not intended to serve as an exhaustive flora of the region; we developed this checklist primarily to facilitate the use of floristic quality assessment in our area. For ease of use, we followed the botanical nomenclature provided in the region's most widely used reference, "Flora of the Great Plains" (Great Plains Flora Association, 1991). We acknowledge that some of the taxonomy is outdated, but given the current state of flux in botanical nomenclature, we decided to standardize our checklist with this widely available printed source which includes keys and detailed descriptions of each taxon. In addition, we are developing an Internet-based version of our checklist to be served from the U.S. Geological Survey's Northern Prairie Wildlife Research Center World Wide Web site (www.npwrc.usgs.gov/resource/2001/fqa/)

fqa.htm) where we intend to provide updated synonyms and species codes standardized with the U.S. Department of Agriculture's PLANTS database (USDA, NRCS, 1999).

We assigned C values (0 to 10) to each taxon of the region's native flora. In assigning coefficients, we followed the guidelines set forth by Taft and others (1997), which are a slight modification of earlier efforts by Swink and Wilhelm (1979, 1994). The C values we assigned represent our collective knowledge of the patterns of occurrence of each plant species in the Dakotas and our confidence that a particular taxon is natural-area dependent. We supplemented our combined field experience by examining range maps and reviewing habitat comments in several references for some taxa (Stevens, 1963; Van Bruggen, 1976; Great Plains Flora Association, 1977, 1991; Larson, 1993). We assigned a coefficient of 0 to weedy species that can flourish in the most highly disturbed habitats (freshly tilled fields, gardens, new road cuts, etc.). Although native to our region, these weedy taxa provided us with 0 confidence that a specimen brought into the herbarium was collected from a remnant natural area. We assigned coefficients ranging from 1 to 4 to taxa that occur in natural areas but also in highly degraded habitats. Thus, a taxon receiving a 3 provided only about 30% confidence that this plant came from a remnant natural area. Taxa to which we assigned coefficients ranging from 5 to 9 are usually found in natural areas but have decreasing degrees of tolerance to disturbance. A taxon with a coefficient of 5 likely came from a natural area, but it could have been a very disturbed natural area, and a taxon receiving a 9 likely came from a relatively undisturbed or otherwise high quality natural area. We reserved the coefficient 10 for those taxa virtually restricted to natural, undisturbed habitats in the Dakotas (i.e., we could be nearly 100% confident that a sample brought into the herbarium was collected from a high quality natural remnant). In the table, we provide examples of species that characterize each C value.

As expected, the differences in plants receiving consecutive coefficients (e.g., 2 and 3) are sometimes slight and hardly discernable. However, concern over whether a plant is assigned a 2 and not a 3 or a 1, for example, is mitigated by averaging values in the actual application of this system (see below). We assigned an asterisk to all nonnative taxa as they are typically excluded from the Floristic Quality Assessment calculations described on page 4. Taxa identified as native on our checklist, but that also occur in our region as escapees from cultivation, should be ranked as nonnative when found in these situations (e.g.,

Juniperus scopulorum, *Juniperus virginiana*, and *Pinus ponderosa*).

Mean C values

By applying the C values provided in the Checklist (page 7) to a plant species list assembled for an area of interest, a mean C value (\bar{C}) can be calculated by summing the C values for each native species present in the survey and dividing the summation by the total number of species present (N):

$$\bar{C} = \frac{\sum C}{N}$$

Thus, \bar{C} represents the average conservatism of the plant community. By repeating surveys and calculating \bar{C} over periods of time, temporal changes in floristic quality can be evaluated. If habitat quality of an area is degrading, the first plants lost from the plant community will be conservative species (i.e., those with the highest C values). These conservative species will be replaced by less conservative species (i.e., those with lower C values), nonnative weeds, or no plants at all and \bar{C} will decline. Alternatively, if habitat quality is improving, the number of conservative species will increase and be reflected by an increase in \bar{C} .

Nonnative species are not used in calculations to estimate the floristic quality of the native plant communities. Because these species did not develop in our region, it is difficult to assess the relationship of their occurrence to habitat integrity. Additionally, some nonnative species such as *Bromus inermis* and *Poa pratensis* are virtually ubiquitous in the region. It is

Table. Plant species characteristic of coefficients of conservatism (C values) ranging from 0 to 10.

C value	Example species
0	<i>Amaranthus retroflexus</i> , <i>Conyza canadensis</i> , <i>Panicum capillare</i>
1	<i>Beckmannia syzigachne</i> , <i>Draba reptans</i> , <i>Solidago canadensis</i>
2	<i>Aster ericoides</i> , <i>Potentilla anserine</i> , <i>Verbena stricta</i>
3	<i>Bidens cernua</i> , <i>Ratibida columnifera</i> , <i>Rosa arkansana</i>
4	<i>Agropyron smithii</i> , <i>Carex eleocharis</i> , <i>Ribes missouriense</i>
5	<i>Andropogon gerardii</i> , <i>Cornus stolonifera</i> , <i>Helianthus maximiliana</i>
6	<i>Eriogonum annuum</i> , <i>Iris missouriensis</i> , <i>Sorghastrum nutans</i>
7	<i>Astragalus crassicaulis</i> , <i>Erysimum inconspicuum</i> , <i>Koeleria pyramidata</i>
8	<i>Heuchera richardsonii</i> , <i>Liatris aspera</i> , <i>Stipa spartea</i>
9	<i>Amorpha nana</i> , <i>Lespedeza capitata</i> , <i>Mertensia lanceolata</i>
10	<i>Cypripedium</i> spp., <i>Trillium</i> spp., <i>Vallisneria americana</i>

better to measure the effect that these species have on the native plant communities by considering them as a disturbance (i.e., measuring their effect indirectly through changes in \bar{C} of the native plant community). If desired, a calculation of \bar{C} can be conducted that includes the nonnative species. In these cases, nonnative species should be assigned a C value of 0, and a separate calculation using only the native species should also be conducted and reported.

Floristic quality index

If one is ranking sites in order of their floristic quality, a method is needed to discriminate among areas with similar \bar{C} 's but that differ significantly in the number of native species each supports. This ranking can be accomplished by calculating a floristic quality index (FQI). FQI is obtained by multiplying \bar{C} by the square root of the number of native species present (N):

$$FQI = \bar{C}\sqrt{N}$$

Thus, FQI is simply a weighted species-richness estimate that uses a square root transformation of N to limit the influence of area alone on species richness (Swink and Wilhelm, 1979, 1994). Two sites may have similar \bar{C} 's but different FQI's or similar FQI's but different \bar{C} 's if the number of native species each supports differs greatly. Calculating values for both \bar{C} and FQI facilitates better comparisons among sites.

Application

Swink and Wilhelm (1994) identified four commonly used applications for the floristic quality assessment system: (1) identification of natural areas, (2) facilitation of comparisons among different sites, (3) long-term monitoring of remnant natural area quality, and (4) evaluating habitat restorations. All four applications involve compiling a plant inventory for a site and then calculating \bar{C} and FQI using C values assigned a priori to each taxon (see checklist, page 7). For monitoring efforts, these inventories can be duplicated yearly or at other intervals deemed appropriate to capture temporal changes in floristic quality. The sampling unit can be as small as a 0.25-m² quadrat along a transect or as large as an entire natural area. The size of the sampling unit depends most often upon project objectives. In the case of an isolated wetland, the unit may be the entire wetland where a botanist would record all species encountered in a complete walkthrough of the basin. However, quadrats randomly placed within each zone may be more appropriate if an assessment of the

wetland's plant communities by vegetative zone is the goal. Because sample area and sampling effort can influence floristic quality assessments, it is important to include details of the survey methodology when reporting \bar{C} and FQI. The details will facilitate meaningful and consistent subsequent comparisons of floristic quality among areas.

Although \bar{C} and FQI each provide useful information for assessing ecosystem integrity, other measurements can provide additional information and should be included in most assessments of floristic quality. Total species richness, native species richness, percent nonnative taxa, and physiognomic composition can also be calculated without additional field work, and each can provide information useful in discriminating between sites or in corroborating trends observed in \bar{C} or FQI (e.g., a decrease in \bar{C} may be accompanied by an increase in the percent of nonnative taxa).

We limited our checklist to the vascular flora of the Dakotas and assigned the C values based on the occurrence of each species within this political boundary. State boundaries usually do not follow ecological boundaries; thus, the C values we provide should be equally valid in nearby areas with the same vegetation types. The glaciated plains of western Minnesota and northwestern Iowa are prime examples of areas where our C values should be applicable. However, the more remote a site is from our core area of consideration, the more likely it will be that our C values will not reflect local conditions and may render misleading results.

Results and discussion

Of the total 1,584 taxa we considered in this effort, 275 (17%) were determined to be nonnative to the region. Of the region's 1,309 native taxa, we assigned a C value of 10 to 20% (figure 1), indicating that these plants are extremely intolerant of disturbance; consequently, these taxa occur only in the highest quality, remnant natural areas of the Dakotas. We assigned C values of 3 or less to 23% of our native taxa, and the entire native flora of the Dakotas had a \bar{C} of 6.1. These results are similar to those found in the Chicago region, other parts of Illinois, and Michigan where 11%, 17%, and 15% (respectively) of the native plant species were assigned C values of 3 or less and the native floras had \bar{C} 's of 7.3, 6.4, and 6.5 (Swink and Wilhelm, 1994; Herman and others, 1997; Taft and others, 1997).

Grouping taxa by physiognomic class reveals that most native species in the Dakotas are perennial forbs, followed by annual forbs, perennial sedges, perennial grasses, and shrubs (figure 2). Conversely, the region's

Figure 1. Distribution of the 1,309 native plant taxa occurring in North and South Dakota (excluding the Black Hills) by coefficient of conservatism designation.

nonnative taxa are dominated by annual forbs. Also, although only 16% of the native grasses are annuals, over half (55%) of the nonnative grass taxa are annuals. Of the 129 perennial grasses in the Dakota region, only 18 (14%) are nonnative; however, of the 44 annual grasses, half are nonnative. Much of the current landscape favors annual plants, whereas annual species were less prevalent in the region's presettlement plant communities. The shift from habitats favorable to perennials to those providing competitive advantages to annuals is clearly reflected in the physiognomic composition of the nonnative plant taxa that have successfully invaded our region.

By applying the coefficients of conservatism supplied here and calculating \bar{C} and FQI, an effective means of evaluating the quality of plant communities in our region is obtained. Changes in quality, either positive or negative, can be identified by repeating surveys and calculations over time. Through the use of floristic quality assessment, for example, a preserve manager reintroducing fire to a landscape in a manner

approximating pre-European settlement conditions can determine, through changes in \bar{C} and FQI, if the change in management is allowing conservative plant species to repopulate the area. Similarly, a regulator attempting to estimate the consequences of draining a wetland can obtain a clearer idea of the likelihood of re-creating a wetland with a comparable plant community elsewhere, and a real estate specialist will have reliable information for ranking tracts of land when acquisition funds are limited.

Floristic quality assessment may help to better focus our efforts in areas of greatest potential benefit as competition for limited natural and financial resources continues. For example, drainage of a wetland with a long history of cropping in the basin during periods of below average precipitation may be easy to mitigate in terms of the native plant communities it supports. The species inhabiting this wetland will be limited to those that can tolerate the extreme disturbances associated with periodic cropping and will quickly repopulate a created or restored basin with minimal effort. However, a similarly sized wetland with soils that have never been tilled may support a native plant community rich in conservative species and be beyond our current abilities to create or restore; loss of this wetland should be considered an immitigable event. Floristic quality assessment allows us to identify high quality natural areas and to measure the quality of native plant communities we have attempted to restore and/or manage, thus providing an objective assessment of our current restoration and management efforts.

Acknowledgments

We would like to thank individuals and agency representatives who attended our November 1999 meeting in Jamestown, North Dakota, and provided their ideas, inspiration, and support. We thank the USGS Northern Prairie Wildlife Research Center for hosting this initial meeting and North Dakota State University for providing use of their facilities for our follow-up workshop in Fargo, North Dakota. This effort would not have been possible without the financial support of the U.S. Department of Agriculture Natural Resources Conservation Service, U.S. Army Corps of Engineers, U.S. Bureau of Reclamation, U.S. Fish and Wildlife Service, and the U.S. Geological Survey. We thank Mark A. Anderson, Robert R. Cox, Jr., Ann L. Dahl, Bruce A. Hanson, and two anonymous individuals for reviewing this manuscript, and Dorothy E. Mushet for providing the cover illustration. Additionally, we thank Dr. Gerould S. Wilhelm for providing his unique insight

Figure 2. Distribution of native and nonnative plant taxa occurring in North and South Dakota (excluding the Black Hills) by physiognomic class.

and guidance throughout this process, especially during our initial meeting in Jamestown and the resulting workshop in Fargo.

Vegetation checklist for North and South Dakota (excluding the Black Hills)

Here we provide a listing of the vascular plant taxa of North and South Dakota (excluding the Black Hills) with our recommended coefficients of conservatism (C). The listing of taxa in our checklist is not intended to serve as an exhaustive flora of the region; we developed this listing for the primary purpose of facilitating use of floristic quality assessment in the Dakotas and adjacent grasslands. For ease of use, we followed the botanical nomenclature provided in the most widely used flora checklist for the Dakotas, "Flora of the Great Plains" (Great Plains Flora Association, 1991). The listing is sorted alphabetically by scientific name. Native taxa are italicized while nonnative taxa are capitalized and also identified by an asterisk in the C column.

Each taxon has been designated a physiognomic grouping (i.e., fern, grass, sedge, forb, vine, shrub, tree). The grasses, sedges, and forbs are further identified as annuals (A), biennials (B), or perennials (P), and the vines are identified as herbaceous (H) or woody (W). Although these designations sometimes imperfectly depict the habit of a plant taxon and are subject to interpretation, they can be useful in identifying structural differences or changes in a plant community.

To further aid the application of floristic quality assessment in the Dakotas, we provide a six-letter acronym for each taxon. Use of these acronyms increases the speed at which field notes can be recorded and allows the direct transfer of field data into currently available floristic quality assessment computer programs. The acronyms are formed from the first three letters of the genus followed by the first three letters of the species or by the first two letters of the species and the first letter of the subspecies. In cases where duplicate acronyms result, we provide a nonintuitive acronym. To avoid excessive duplication in the *Carex* genus, we used CX followed by the first four letters of the species.

Acronym	C	Scientific Name	Common Name	Physiognomy	Family

13. ABSTRACT (Maximum 200 words) Floristic quality assessment can be used to identify natural areas, to facilitate comparisons among different sites, to provide long-term monitoring of natural area quality, and to evaluate habitat management and restoration efforts. To facilitate the use of floristic quality assessment in North Dakota, South Dakota (excluding the Black Hills), and adjacent grasslands, we developed a species list and assigned coefficients of conservatism (C values; range = 0 to 10) to each plant species in the region's flora. The C values we assigned represented our collective knowledge of the patterns of occurrence of each plant species in the Dakotas and our confidence that a particular taxon is natural-area dependent. Because state boundaries usually do not follow ecological boundaries, the C values we assigned should be equally valid in nearby areas with the same vegetation types. Of the 1,584 taxa we recognized in this effort, 275 (17%) were determined to be nonnative to the region. We assigned C values of 4 or higher to 77% of our native taxa, and the entire native flora had a mean C value (\bar{C}) of 6.1. A floristic quality index (FQI) can be calculated to rank sites in order of their floristic quality. By applying the coefficients of conservatism supplied here and calculating \bar{C} and FQI, an effective means of evaluating the quality of plant communities can be obtained. Additionally, by repeating plant surveys and calculations of \bar{C} and FQI over time, temporal changes in floristic quality can be identified.

Technical Report Series

The Biological Resources Division publishes scientific and technical articles and reports resulting from the research performed by our scientists and partners. These articles appear in professional journals around the world. Reports are published in two report series: Biological Science Reports and Information and Technology Reports.

Series Descriptions

Biological Science Reports

ISSN 1081-292X

This series records the significant findings resulting from sponsored and cosponsored research programs. They may include extensive data or theoretical analyses. Papers in this series are held to the same peer-review and high quality standards as their journal counterparts.

Information and Technology Reports ISSN 1081-2911

These reports are intended for publication of book-length monographs; synthesis documents; compilations of conference and workshop papers; important planning and reference materials such as strategic plans, standard operating procedures, protocols, handbooks, and manuals; and data compilations such as tables and bibliographies. Papers in this series are held to the same peer-review and high quality standards as their journal counterparts.

U.S. Department of the Interior

U.S. Geological Survey

As the Nation's principal conservation agency, the Department of the Interior has responsibility for most of our nationally owned public lands and natural resources. This responsibility includes fostering the sound use of our lands and water resources; protecting our fish, wildlife, and biological diversity; preserving the environmental and cultural values of our national parks and historical places; and providing for the enjoyment of life through outdoor recreation. The Department assesses our energy and mineral resources and works to ensure that their development is in the best interests of all our people by encouraging stewardship and citizen participation in their care. The Department also has a major responsibility for American Indian reservation communities.
